

This is a highly effective strategy known as **Local Entitlement Management**. It ensures that the transition from a trial to a paywall is seamless, regardless of the user's connection status.

How it Works

- **The Offline Timer:** You store a "Trial Start Timestamp" in the app's local secure storage (like EncryptedShaders or Keychain). The app compares this to the current system clock to trigger the paywall after 48 hours.
- **The Hard Wall:** Once the timer hits zero, the app locks premium features locally. Even if the user is in a "dead zone," the app remains locked.
- **The Online Bridge:** When the user clicks "Upgrade," the app checks for a connection. If offline, it displays a friendly message: *"You've reached the end of your trial! Please connect to the internet briefly to activate your full license."*

Pros and Cons

Feature	Benefit	Risk
Trust	Users see that the app respects their time and works without constant "pinging."	Users can technically "cheat" by changing their device's system date (though you can prevent this by checking uptime).
Continuity	The user experience is predictable.	If a user needs the app for an emergency while offline and the trial ends, they are stuck.

Refinement Suggestion

To avoid leaving a visually impaired user stranded in an emergency, consider a **"Safety Extension."** If the trial ends while the user is offline, give them **one extra hour** of access specifically to find a safe place or a Wi-Fi connection.

Would you like me to outline the logic for a "Safety Extension" feature for your developers?
